## Batch Scheduling

## PROBLEM

There is a sequence of $N$ jobs to be processed on one machine. The jobs are numbered from 1 to $N$, so that the sequence is $1,2, \ldots, N$. The sequence of jobs must be partitioned into one or more batches, where each batch consists of consecutive jobs in the sequence. The processing starts at time 0 . The batches are handled one by one starting from the first batch as follows. If a batch $b$ contains jobs with smaller numbers than batch $c$, then batch $b$ is handled before batch $c$. The jobs in a batch are processed successively on the machine. Immediately after all the jobs in a batch are processed, the machine outputs the results of all the jobs in that batch. The output time of a job $j$ is the time when the batch containing $j$ finishes.

A setup time $S$ is needed to set up the machine for each batch. For each job $i$, we know its cost factor $F_{i}$ and the time $T_{i}$ required to process it. If a batch contains the jobs $x, x+1$, $\ldots, x+k$, and starts at time $t$, then the output time of every job in that batch is $t+S+\left(T_{x}\right.$ $+T_{x+1}+\ldots+T_{x+k}$ ). Note that the machine outputs the results of all jobs in a batch at the same time. If the output time of job $i$ is $O_{i}$, its cost is $O_{i} \times F_{i}$. For example, assume that there are 5 jobs, the setup time $S=1,\left(T_{1}, T_{2}, T_{3}, T_{4}, T_{5}\right)=(1,3,4,2,1)$, and $\left(F_{1}, F_{2}, F_{3}\right.$, $\left.F_{4}, F_{5}\right)=(3,2,3,3,4)$. If the jobs are partitioned into three batches $\{1,2\},\{3\},\{4,5\}$, then the output times $\left(O_{1}, O_{2}, O_{3}, O_{4}, O_{5}\right)=(5,5,10,14,14)$ and the costs of the jobs are $(15,10,30,42,56)$, respectively. The total cost for a partitioning is the sum of the costs of all jobs. The total cost for the example partitioning above is 153 .

You are to write a program which, given the batch setup time and a sequence of jobs with their processing times and cost factors, computes the minimum possible total cost.

## INPUT

Your program reads from standard input. The first line contains the number of jobs $N, 1$ $\leq N \leq 10000$. The second line contains the batch setup time $S$ which is an integer, $0 \leq S$ $\leq 50$. The following $N$ lines contain information about the jobs $1,2, \ldots, N$ in that order as follows. First on each of these lines is an integer $T_{i}, 1 \leq T_{i} \leq 100$, the processing time of the job. Following that, there is an integer $F_{i}, 1 \leq F_{i} \leq 100$, the cost factor of the job.

## OUTPUT

Your program writes to standard output. The output contains one line, which contains one integer: the minimum possible total cost.

Korea

## EXAMPLE INPUTS AND OUTPUTS

Example 1: input

| 2 |  |
| :--- | :--- |
| 50 |  |
| 100 | 100 |
| 100 | 100 |

100100
100100
output

45000

Example 2: input

| 5 |  |
| :--- | :--- |
| 1 |  |
| 1 | 3 |
| 3 | 2 |
| 4 | 3 |
| 2 | 3 |
| 1 | 4 |

output 153

Example 2 is the example in the text.

## REMARK

For each test case, the total cost for any partitioning does not exceed $2^{31}-1$.

## SCORING

If your program outputs the correct answer for a test case within the time limit, then you get full points for the test case, and otherwise you get 0 points.
